Abstract
Using a Coons patch mapping to generate the structured grid in the parametric region of a trimmed surface can avoid the singularity of elliptic PDE methods when only $C^1$ continuous boundary is given; the error of converting generic parametric $C^1$ boundary curves into a specified representation form is also avoided. However, overlap may happen on some portions of the algebraically generated grid when a linear or naïve cubic blending function is used in the mapping; this severely limits its usage in most of engineering and scientific applications where a grid system of non-self-overlapping is strictly required. To solve the problem, non-trivial blending functions in a Coons patch mapping should be determined adaptively by the given boundary so that self-overlapping can be averted. We address the adaptive determination problem by a functional optimization method. The governing equation of the optimization is derived by adding a virtual dimension in the parametric space of the given trimmed surface. Both one-parameter and two-parameter blending functions are studied. To resolve the difficulty of guessing good initial blending functions for the conjugate gradient method used, a progressive optimization algorithm is then proposed which has been shown to be very effective in a variety of practical examples. Also, an extension is on the objective function to control the element shape. Finally, experiment results are shown to illustrate the usefulness and effectiveness of the presented method.

Keywords: algebraic grid generation, trimmed surface, parametric space, self-overlap, and Coons patch

1. Introduction

This paper presents a method for generating algebraic grids on a trimmed surface by fitting a non-self-overlapping planar Coons patch into the parametric region of the given surface. In computer-aided engineering, geometric modeling, computer graphics, and many other applications, a parametric surface patch usually intersects with other surfaces, and thus only a portion of the surface patch is used in defining a meaningful shape [1]. The remaining portion of parametric surface patch \( S \) after trimming by other surfaces is called a trimmed (parametric) surface \( S_T \). \( S_T \) is constrained by the same mathematical surface equation as \( S(u,v) \), but its parametric domain is only a portion of that of \( S \). The parametric area of \( S_T - P_{S_T} \) lies inside \((u,v) \in [0,1] \times [0,1]\) (assuming the \( u-v \) domain of \( S \) is normalized) and is bounded by a number of curves (see Fig. 1-1). Each boundary curve of \( P_{S_T} \) is expressed as a parametric equation of the form \( b_i = [u_i(t) \ v_i(t)] \), where \( t \in [0,1] \).

![Fig. 1-1 A trimmed surface and its related parametric area](image)

An essential task in many engineering disciplines is to approximate a trimmed surface by an aggregate of simple planar elements, e.g., triangles and quadrilateral elements; this is referred to as the surface meshing operation. Surface mesh generation methods have been studied for many years. Both structured and unstructured grids can be constructed on three-dimensional surfaces [2]. The two most powerful analysis tools in engineering are the finite element method and the finite difference method. The finite element method usually conducts either triangular grids or quadrilateral grids, and the grids can be structured or unstructured. Quadrilateral grids in general have better quality than the triangular grids. Unstructured 2D quadrilateral grids can be constructed directly by geometry decomposition [3-6], boundary advancing [7-10], and skeleton construction [11, 12]; or indirectly by the background triangular grids [13-17]. However, the finite difference method generally uses structured quadrilateral grids (or simply called structured grids). The structured grids can be generated...
algebraically or as the solution of Partial Differential Equations (PDEs). Algebraic grid generation is some form of interpolation from boundary points – different approaches use different kinds of interpolation [18-20]. Overlap may, however, happen on some portions of algebraically generated grids. Also, error may be generated when converting generic boundary curves into curves with a specified representation. Grid generation is actually a boundary-value problem, so grids can be generated from point distribution on boundaries by solving elliptic PDEs in the field [21-25]. The smoothness properties and extremum principles of some such PDE systems can serve to produce smooth grids without boundary overlap. However, since the elliptic PDE methods require second derivative, singularity appears when any boundary curve of $P_{S_{T}}$ is only $C^1$ continuity.

Similar to other algebraic grid generation approaches, our grid construction method also consists of three steps: 1) forward mapping; 2) grid generation; and 3) back mapping. The forward mapping is the mapping of the three-dimensional physical surface $S_{T}$ to its underlying parametric area $P_{S_{T}}$. Once the forward mapping is finished, the grids are produced in $P_{S_{T}}$ by fitting a planar Coons patch $X(\xi, \eta)$. After establishing the uniform $M \times N$ grid in the parametric domain of $S_{C}(\xi, \eta)$ by

$$\begin{align*}
\frac{\xi_i}{M} &= \frac{i}{M} (i = 0, \cdots, M) \\
\frac{\eta_j}{N} &= \frac{j}{N} (j = 0, \cdots, N),
\end{align*}$$

(1-1)

the $M \times N$ grid on the physical trimmed space can be expressed by the back mapping in the form

$$S_{T_{ij}} = S(u(X(\xi_i, \eta_j)), v(X(\xi_i, \eta_j))),$$

(1-2)

where the functions $u(\cdots)$ and $v(\cdots)$ represent the $u$ and $v$ coordinates of a point on the Coons patch. However, as mentioned above, overlap may happen on the boundary of $P_{S_{T}}$ or even in the middle of $P_{S_{T}}$, which of course influences the final surface grid (see Fig. 1-2). Aimed at resolving this perplexing issue, a method based on finding proper blending functions in $X(\xi, \eta)$ is explored in this paper, which assures the non-self-overlapping property. Since using a Coons patch does not need to convert the representation of boundary curves, no converting error is generated in this method. For the $P_{S_{T}}$ with complex boundaries, the whole $P_{S_{T}}$ can be subdivided into several sub-regions, where each region has only four boundary curves and its corner points satisfy the non-self-overlapping condition.

We organize the paper as follows. In section 2, some necessary definitions and preliminaries are first given. Next, the governing equation is derived in section 3 by the normal of the Coons patch in a virtual direction $-w$. 

3
Based on the governing equation, the formulas to compute the functional optimum of one-parameter blending functions in the Coons patch is presented in section 4; and in section 5, the blending functions are extended to two-parameter functions to achieve more flexibility. In section 6, to overcome the difficulty of “guessing” a good initial blending function, an algorithm for computing the optimum progressively is given. Finally, section 7 shows the possible extension of our method to control the shape of elements.

**Fig. 1-2** Overlap occurs near the boundary or in the middle of \( P_s \).

### 2. Preliminary

We first give necessary definitions and preliminaries.

**Definition 2.1** Given four \( C^1 \) curves \( Q_0(\xi) \), \( Q_1(\xi) \), \( P_0(\eta) \) and \( P_1(\eta) \) \( (0 \leq \xi, \eta \leq 1) \) in three-dimensional space that form a closed curve, the *Coons patch* defined on them is

\[
X(\xi, \eta) = [\alpha(\xi) - \alpha(\xi)] \begin{bmatrix} P_0(\eta) \\ P_1(\eta) \end{bmatrix} + [Q_0(\xi) \quad Q_1(\xi)] \begin{bmatrix} \beta(\eta) \\ 1 - \beta(\eta) \end{bmatrix} - [\alpha(\xi) - \alpha(\xi)] \begin{bmatrix} Q_0(0) \\ Q_0(1) \end{bmatrix} \begin{bmatrix} \beta(\eta) \\ 1 - \beta(\eta) \end{bmatrix}
\]

where \( \alpha(\xi) \) is a \( C^1 \) function of \( \xi \) in \([0, 1]\) satisfying \( \alpha(0) = 1 \) and \( \alpha(1) = 0 \), \( \beta(\eta) \) is a \( C^1 \) function of \( \eta \) in \([0, 1]\) satisfying \( \beta(0) = 1 \) and \( \beta(1) = 0 \), and the parametric space of the Coons patch is \( (\xi, \eta) \in [0, 1] \times [0, 1] \).
The two functions $\alpha(\xi)$ and $\beta(\eta)$ are referred to as the blending functions of a Coons patch. As the four curves are all $C^1$ continuous, $X(\xi, \eta)$ has partial derivatives in the entire parameter domain. By its definition, it can be easily verified that the mapping $X(\xi, \eta)$ is boundary conforming; that is, we have $X(0,0) = Q_0(\xi)$, $X(0,1) = Q_1(\xi)$, $X(0,\eta) = P_0(\eta)$, and $X(1,\eta) = P_1(\eta)$. Therefore, $Q_0(\xi)$, $Q_1(\xi)$, $P_0(\eta)$ and $P_1(\eta)$ are the boundary curves of the corresponding Coons patch.

In $X(\xi, \eta)$, the four curves are connected in the way that $Q_0(1) = P_1(0)$, $P_1(1) = Q_1(0)$, $Q_1(0) = P_0(1)$, and $P_0(0) = Q_0(0)$ (illustrated in Fig. 2-1); points $Q_0(0)$, $Q_0(1)$, $Q_1(0)$, and $Q_1(1)$ are the corner points of $X(\xi, \eta)$. Since the four curves are given conditions, they cannot be changed in our computation. The blending function $\alpha(\xi)$ gives an interpolation between $P_0(\eta)$ and $P_1(\eta)$, and $\beta(\eta)$ gives the interpolation between $Q_0(\xi)$ and $Q_1(\xi)$. They are not restricted to be one-parameter functions though; two-parameter functions can also be used.

If the four boundary curves of a Coons patch $X(\xi, \eta)$ all lie in a common plane, obviously $X(\xi, \eta)$ also lies in that plane, i.e., it is a planar Coons patch. Unless specially noted in the context, hereafter a planar Coons patch is assumed. As it is planar, the set of all the points of $X(\xi, \eta)$ for $(\xi, \eta) \in [0,1] \times [0,1]$, denoted as $\Omega_X$, form a compact region in the $u-v$ plane. On the other hand, since the four defining curves of $X(\xi, \eta)$ – $Q_0(\xi)$, $Q_1(\xi)$, $P_0(\eta)$ and $P_1(\eta)$ – also all lie in this same plane, they enclose a simple region $\Omega$. We next define an important criterion on the relationship between the two regions.

**Definition 2.2** A Coons patch $X(\xi, \eta)$ is said to be a graph-mapping if it is a one-to-one mapping between the square $[0,1] \times [0,1]$ in the $\xi-\eta$ plane and the region $\Omega_X$. 
Since an $X(\xi, \eta)$ is always boundary conforming, one can prove that the two regions $\Omega_X$ and $\Omega$ are identical to each other if $X(\xi, \eta)$ is a graph-mapping. Moreover, because a graph-mapping $X(\xi, \eta)$ is one-to-one, one can mesh the region $\Omega_X$, and hence $\Omega$, by simply first uniformly meshing the square $[0, 1] \times [0, 1]$ in the $\xi - \eta$ plane and then map this mesh to $\Omega_X$ (and $\Omega$) by the mapping $X(\xi, \eta)$, which is guaranteed to be free of self-overlapping. As $\Omega$ can be taken as the parametric area in the $u - v$ plane of a trimmed surface $S_T$, a meshing of $\Omega$ thus introduces a valid meshing of $S_T$.

But, exactly how should this graph-mapping be rigorously and mathematically characterized? This calls for the introduction of the governing function as described in the next section.

3. Governing Equation

In this section, the governing equation to eliminate the self-overlap is derived. Let’s add a virtual axis $w$ perpendicular to the $u - v$ plane, i.e., $w = u \times v$. A Coons patch $X(\xi, \eta)$ now is a planar region embedded in the $u \times v \times w$ space, denoted as $X(\xi, \eta) = \begin{bmatrix} U(\xi, \eta) \\ V(\xi, \eta) \\ W(\xi, \eta) \end{bmatrix}$, where $U(\xi, \eta)$, $V(\xi, \eta)$, and $W(\xi, \eta)$ are the components of $X(\xi, \eta)$ on the $u, v$, and $w$ axis respectively (note that $W(\xi, \eta)$ is a constant zero). We define the unit “normal vector” at any point $(\xi_0, \eta_0)$ on the patch $X(\xi, \eta)$ as $N(\xi_0, \eta_0) = \frac{X_\xi \times X_\eta}{\|X_\xi \times X_\eta\|}(\xi_0, \eta_0)$. A point $(\xi_0, \eta_0)$ is said to be singular if its corresponding $\|X_\xi \times X_\eta\|$ is a zero vector. The lemma below is important as it stipulates the condition for guaranteeing the graph-mapping property.

**Lemma 3.1** The Coons patch $X(\xi, \eta) = \begin{bmatrix} U(\xi, \eta) \\ V(\xi, \eta) \\ W(\xi, \eta) \end{bmatrix}$ is a graph-mapping if and only if there is no any singular point in the square $[0, 1] \times [0, 1]$.

(The proof is given in Appendix A)
Based on the above lemma, the following useful proposition is in order.

**Proposition 3.1** If the normal at every point to the Coons patch \(X(\xi, \eta)\) has the same sign in \(w\), then \(X(\xi, \eta)\) is a graph-mapping.

Without loss of generality, we can assume that the sign in \(w\) of the normal vectors of a graph-mapping \(X(\xi, \eta)\) is always positive. To facilitate the formulation, we use the following two definitions.

**Definition 3.1** A point \((\xi_d, \eta_d)\) is called a shadow point of \(X(\xi, \eta)\) if the normal at \((\xi_d, \eta_d)\) is along the negative \(w\)-axis.

**Definition 3.2** The set \(R_d\) of all the shadow points of \(X(\xi, \eta)\) is defined as the shadow region of \(X(\xi, \eta)\).

Shadow points must be prevented at the corners. It is because the normal direction at a corner point is determined and only determined by the two tangents on its related two boundary curves. No matter how you change the blending functions of the Coons patch, the tangents on the boundary curves are not changed. Thus, the following assumption is imposed on the four defining curves.

**Assumption 3.1** The normals of \(Q_0, Q_1, P_0,\) and \(P_1\) at the four corners respectively are along the positive \(w\)-axis.

From the above analysis, we find that the governing equation should be a function indicating the area of the shadow region of \(X(\xi, \eta)\). Since the projection of \(X_\xi \times X_\eta\) along the \(w\)-axis is \(X_{\xi_w}, X_{\eta_w}, X_{\xi_\eta}\) (where \(X_{\xi_w} = U_{\xi}, X_{\eta_w} = U_{\eta}, X_{\xi_\eta} = V_{\xi}\), and \(X_{\eta_\eta} = V_{\eta}\)), the final governing equation to construct a non-self-overlapping planar Coons patch on four given boundaries is

\[
\int_\Psi \text{H}[-(X_{\xi_w} X_{\eta_w} - X_{\eta_\eta} X_{\xi_\eta})] d\xi d\eta = 0, \tag{3-1}
\]

where \(\text{H}(\cdot)\) is the Heaviside function, and \(\Psi\) is the overall domain of \((\xi, \eta) \in [0, 1] \times [0, 1]\). Actually, the left part of equation (3-1) is exactly the area of the shadow region in the \(u - v\) space.

4. One-parameter Blending Function

To achieve (3-1), we use the functional optimization method to determine the algebraic function of a non-self-overlapping planar Coons patch within the Jordan curve formed by \(Q_0(\xi), Q_1(\xi), P_0(\eta),\) and \(P_1(\eta)\). In
the definition of a Coons patch, only the two blending functions, i.e., \( \alpha(\xi) \) and \( \beta(\eta) \), are flexible to be changed during the optimization. As polynomials are most widely used in computer-aided geometric design due to its many merits, we also use polynomials for the blending functions. They are one-parameter functions. Thus, the following proposition comes.

**Proposition 4.1** If a blending function \( \alpha(\xi) \) of degree \( n \) in \( \xi \) direction and a blending function \( \alpha(\eta) \) of degree \( m \) in \( \eta \) direction are used, we have totally \( n + m - 2 \) degree of freedom to control the distribution of grid points inside \( X(\xi, \eta) \) in the \( u - v \) parametric space.

When \( \alpha(\xi) \) is a polynomial of degree \( n \), it can be represented by \( \alpha(\xi) = \sum_{i=0}^{n} a_i \xi^i \). Since \( \alpha(\xi) \) should satisfy \( \alpha(0) = 1 \) and \( \alpha(1) = 0 \), we can determine that \( a_0 = 1 \) and \( a_i = -\sum_{i=2}^{n} a_i \). Therefore, \( \alpha(\xi) \) is expressed as

\[
\alpha(\xi) = 1 - (1 + \sum_{i=2}^{n} a_i)\xi^i + \sum_{i=2}^{n} a_i \xi^i
\]

(4-1)

where \( a_i, i = 2, ..., n \), are variables to be determined. Similarly, we can represent \( \beta(\eta) \) by

\[
\beta(\eta) = 1 - (1 + \sum_{j=2}^{m} b_j)\eta^j + \sum_{j=2}^{m} b_j \eta^j
\]

(4-2)

where \( b_j, j = 2, ..., m \), are variables to be determined. Therefore, totally \( n + m - 2 \) variables can be adjusted to determine the optimized algebraic function of \( X(\xi, \eta) \); they form the solution vector of the functional optimization as \( \chi = [a_2 \cdots a_n \ b_2 \cdots b_m] \).

From the governing equation (3-1), the objective function in the functional optimization is given as

\[
A = \iint_{\Omega} \sum_{\xi, \eta} H[-(X_{\xi, \eta} X_{\eta, \xi} - X_{\eta, \xi} X_{\xi, \eta})]d\xi d\eta
\]

(4-3)

From the definition of Coons patch (Definition 2.1), the partial derivatives of \( X(\xi, \eta) \) are

\[
\frac{\partial X(\xi, \eta)}{\partial \xi} = \left[ \begin{array}{c}
U_{\xi} \\
V_{\xi}
\end{array} \right] = \left[ \begin{array}{c}
\alpha'(\xi) - \alpha'(\xi) \\
\beta'(\eta) - \beta'(\eta)
\end{array} \right]
\]

and

\[
\frac{\partial X(\xi, \eta)}{\partial \eta} = \left[ \begin{array}{c}
P_{0}(\eta) \\
Q_{0}(\eta)
\end{array} \right] + \left[ \begin{array}{c}
Q_{0}(\xi) \\
P_{0}(\xi)
\end{array} \right] \left[ \begin{array}{c}
\alpha'(\eta) \\
\beta'(\eta)
\end{array} \right] - \left[ \begin{array}{c}
\alpha'(\xi) \\
\beta'(\xi)
\end{array} \right]
\]

\[
\left[ \begin{array}{c}
Q_{0}(0) \\
Q_{0}(1)
\end{array} \right] \left[ \begin{array}{c}
\beta(\eta)
\end{array} \right] - \left[ \begin{array}{c}
Q_{0}(0) \\
Q_{0}(1)
\end{array} \right] \left[ \begin{array}{c}
\beta(\eta)
\end{array} \right] \left[ \begin{array}{c}
1 - \beta(\eta)
\end{array} \right]
\]
\[ X_\eta = \frac{\partial X(\xi, \eta)}{\partial \eta} = \begin{bmatrix} U_\eta \\ V_\eta \end{bmatrix} = \alpha(\xi) \begin{bmatrix} P_0(\eta) \\ P_1(\eta) \end{bmatrix} + \begin{bmatrix} Q_0(\xi) \\ Q_1(\xi) \end{bmatrix} \begin{bmatrix} \beta'(\eta) \\ -\beta'(\eta) \end{bmatrix} = \begin{bmatrix} \alpha(\xi) \\ 1-\alpha(\xi) \end{bmatrix} \begin{bmatrix} Q_0(0) \\ Q_0(1) \end{bmatrix} \begin{bmatrix} \beta'(\eta) \\ -\beta'(\eta) \end{bmatrix}. \]

From (4-1) and (4-2), we obtain \( \alpha'(\xi) = -1 - \sum_{i=2}^{n} a_i + \sum_{i=2}^{n} i a_i \xi^{i-1} \) and \( \beta'(\eta) = -1 - \sum_{j=2}^{m} b_j + \sum_{j=2}^{m} b_j \eta^{j-1} \), after substituting them into \( X_\xi(\xi, \eta) \) and \( X_\eta(\xi, \eta) \), the following formulas are determined.

\[ X_\xi(\xi, \eta) = (P_0(\eta) - P_1(\eta)) \left[ -1 - \sum_{i=2}^{n} a_i + \sum_{i=2}^{n} i a_i \xi^{i-1} \right] + Q_0(\xi) + (Q_0(\xi) - Q_1(\xi)) \left[ -1 - \sum_{j=2}^{m} b_j + \sum_{j=2}^{m} b_j \eta^{j-1} \right] \]

\[ X_\eta(\xi, \eta) = P'_0(\eta) + (P'_0(\eta) - P'_1(\eta)) \left[ -1 - \sum_{i=2}^{n} a_i \xi^{i-1} + \sum_{i=2}^{n} a_i \xi^i \right] + (Q'_0(\xi) - Q'_1(\xi)) \left[ -1 - \sum_{j=2}^{m} b_j + \sum_{j=2}^{m} b_j \eta^{j-1} \right] \]

By the above formulas, the objective function to determine a non-self-overlapping planar Coons patch can be computed numerically. When optimizing the planar Coons patch, we conduct the Conjugate Gradient Method [27] to search for the final solution vector in the problem space. From (4-3), the gradient direction of \( \chi \) is

\[ \frac{\partial \chi}{\partial a_i} = \int_{\delta} \delta[-(X_\xi X_\eta - X_{\eta X_\xi})] \left( \frac{\partial X_\xi}{\partial a_i} X_\eta + \frac{\partial X_\eta}{\partial a_i} X_\xi \right) \delta d\xi d\eta, \]

\[ \frac{\partial \chi}{\partial b_j} = \int_{\delta} \delta[-(X_\xi X_\eta - X_{\eta X_\xi})] \left( \frac{\partial X_\xi}{\partial b_j} X_\eta + \frac{\partial X_\eta}{\partial b_j} X_\xi \right) \delta d\xi d\eta, \]

where \( \delta(t) = \frac{d}{dt} H(t) \). To calculate the equations (4-6) and (4-7), we need the formulas of \( \frac{\partial X_\xi}{\partial a_i}, \frac{\partial X_\eta}{\partial a_i}, \frac{\partial X_\xi}{\partial b_i}, \frac{\partial X_\eta}{\partial b_i}, \)

and \( \frac{\partial X_\xi}{\partial b_i} \). They are determined from (4-4) and (4-5) as

\[ \frac{\partial X_\xi(\xi, \eta)}{\partial a_i} = \begin{bmatrix} P_0(\eta) - P_1(\eta) \\ Q_0(0) - Q_0(1) \end{bmatrix}^{T} \begin{bmatrix} \alpha(\xi) \\ 1-\alpha(\xi) \end{bmatrix} \begin{bmatrix} Q_0(0) \\ Q_0(1) \end{bmatrix} = \begin{bmatrix} 1-\alpha(\xi) \\ \alpha(\xi) \end{bmatrix} \begin{bmatrix} Q_0(0) \\ Q_0(1) \end{bmatrix} \begin{bmatrix} \beta'(\eta) \\ -\beta'(\eta) \end{bmatrix}. \]
\[
\frac{\partial X_y(\xi, \eta)}{\partial a_j} = P'_0(\eta) - P'_1(\eta) - (Q_0(0) - Q_1(0)) + (Q_0(1) + Q_1(1))\left(-1 - \sum_{j=2}^{n} b_j + \sum_{j=2}^{n} j b_j \eta^{j-1}\right)(-\xi + \xi^i), \quad (4-9)
\]

\[
\frac{\partial X_z(\xi, \eta)}{\partial b_j} = \left[Q'_0(\xi) - Q'_1(\xi) - (Q_0(0) - Q_1(0) - Q_0(1) + Q_1(1))\left(-1 - \sum_{i=2}^{n} a_i + \sum_{i=2}^{n} i a_i \xi^{i-1}\right)\right](-\eta + \eta^i), \quad (4-10)
\]

\[
\frac{\partial X_y(\xi, \eta)}{\partial b_j} = \left[Q_0(\xi) - Q_1(\xi) - \left(1 - \sum_{i=2}^{n} a_i \xi + \sum_{i=2}^{n} a_i \xi^i\right)\right]^{n}T\left[Q_0(0) - Q_1(0)\right]^{\gamma T}\left[Q_0(1) - Q_1(1)\right](-1 + j \eta^{j-1}). \quad (4-11)
\]

The final optimized algebraic functions of \(X(\xi, \eta)\) are computed iteratively; when \(A / \overline{A} < \mu\), the iteration stops (where \(A\) is the value of objective function, and \(\overline{A}\) is the area of the Coons patch \(X(\xi, \eta)\)). \(\mu\) is an empirical threshold number and in our system is set to 0.125%. To have the tendency to compute a global minimization, the following approximation for \(H(t)\) and \(\delta(t)\) are usually adopted [28]:

\[
H_\varepsilon(t) = \frac{1}{2} \left(1 + \frac{2}{\pi} \arctan\left(\frac{t}{\varepsilon}\right)\right), \quad (4-12)
\]

\[
\delta_\varepsilon(t) = \frac{\varepsilon}{\pi (\varepsilon^2 + t^2)}. \quad (4-13)
\]

As \(\varepsilon \rightarrow 0\), the approximation converges to give theoretical \(H(t)\) and \(\delta(t)\). In our testing examples, we usually use \(\varepsilon = \frac{1}{\pi}\), which makes \(\delta_\varepsilon(0) = 1\). The figures of \(H_\varepsilon(t)\) and \(\delta_\varepsilon(t)\) with \(\varepsilon = \frac{1}{\pi}\) are given as below.

![Fig. 4-1 Approximation of \(H(t)\) and \(\delta(t)\)](image)
Fig. 4-2 shows an example of the grid (in $u-v$ plane) generated before and after the functional optimization when choosing $n = m = 4$. At the beginning of the functional optimization, we initially choose $\alpha(\xi) = 1 - \xi$ and $\beta(\eta) = 1 - \eta$, which are straight lines (see Fig. 4-2b). After the functional optimization, they become polynomial curves of degree four (Fig. 4-2c). As demonstrated in the figure, the new non-linear blending functions successfully eliminate the self-overlapping.
5. Two-parameter Blending Function

In our above solution, the blending function between \( P_0(\eta) \) and \( P_1(\eta) \), \( \alpha(\xi) \), is independent of \( \eta \) and the blending function between \( Q_0(\xi) \) and \( Q_1(\xi) \), \( \beta(\eta) \), is independent of \( \xi \), which makes the Coons patch not flexible enough to the given boundary curves. In this section, we explore the feasibility of dedicating the two blending functions as functions of both parameters, i.e., they become \( \alpha(\xi, \eta) \) and \( \beta(\xi, \eta) \). Accordingly, the equation of the planar Coons patch \( X(\xi, \eta) \) changes to

\[
X(\xi, \eta) = \left[ \alpha(\xi, \eta) \begin{bmatrix} P_0(\eta) \\ P_1(\eta) \end{bmatrix} + \beta(\eta, \xi) \begin{bmatrix} 0 \\ 1 \end{bmatrix} \right] - \left[ \alpha(\xi, \eta) \begin{bmatrix} 0 \\ 1 \end{bmatrix} - \alpha(\xi, \eta) \begin{bmatrix} 1 \\ 0 \end{bmatrix} \right] \left[ \begin{bmatrix} Q_0(0) \\ Q_1(0) \end{bmatrix} \begin{bmatrix} Q_0(1) \\ Q_1(1) \end{bmatrix} \begin{bmatrix} 1 - \beta(\xi, \eta) \\ 1 \end{bmatrix} \right],
\]

(5-1)

where \( \alpha(\xi, \eta) \) and \( \beta(\xi, \eta) \) should also satisfy the constraints of Coons patch:

\[
\alpha(0, \eta) = 1, \quad \alpha(1, \eta) = 0, \quad \beta(\xi, 0) = 1, \quad \beta(\xi, 1) = 0 \quad (\xi, \eta \in [0, 1] \times [0, 1]).
\]

Here, we express \( \alpha(\xi, \eta) \) and \( \beta(\xi, \eta) \) as

\[
\alpha(\xi, \eta) = \sum_{i=0}^{m} \sum_{j=0}^{n} a_{i,j} B_{i,m}(\xi) B_{j,n}(\eta), \quad (5-2)
\]

\[
\beta(\xi, \eta) = \sum_{i=0}^{m} \sum_{j=0}^{n} b_{i,j} B_{i,m}(\xi) B_{j,n}(\eta), \quad (5-3)
\]

where \( B_{i,m}(\xi) \) and \( B_{j,n}(\eta) \) are Bernstein basis functions of degree \( m \) and \( n \) – \( j \leq k \leq j \). To satisfy the constraints of Coons patch for \( \alpha(\xi, \eta) \) and \( \beta(\xi, \eta) \), by the properties of Bernstein basis function [1], we have \( a_{0,j} = 1, \ a_{m,j} = 0, \ b_{i,0} = 1 \), and \( b_{i,n} = 0 \). Thus, \( a_{i,j} \) (\( i = 1, \ldots, m-1 \) and \( j = 0, \ldots, n \)) and \( b_{i,j} \) (\( i = 0, \ldots, m \) and \( j = 1, \ldots, n-1 \)) are variables to be determined.

Recall the objective function

\[
A = \int_{\Sigma} H[\cdot \cdot (X_{\xi, \eta} - X_{\eta, \xi})] d\xi d\eta,
\]

during the optimization, the following formulas of partial derivatives of \( X(\xi, \eta) \) are needed.

\[
X_{\xi}(\xi, \eta) = \left[ \alpha_{\xi}(\xi, \eta) - \alpha_{\xi}(\xi, \eta) \right] \begin{bmatrix} P_0(\eta) \\ P_1(\eta) \end{bmatrix} + \left[ \begin{bmatrix} Q_0(0) \\ Q_1(0) \end{bmatrix} \begin{bmatrix} Q_0(0) \\ Q_1(0) \end{bmatrix} \begin{bmatrix} 1 - \beta(\xi, \eta) \\ 1 \end{bmatrix} \right] - \left[ \alpha(\xi, \eta) - \alpha(\xi, \eta) \right] \left[ \begin{bmatrix} Q_0(0) \\ Q_1(0) \end{bmatrix} \begin{bmatrix} Q_0(1) \\ Q_1(1) \end{bmatrix} \begin{bmatrix} 1 - \beta(\xi, \eta) \\ 1 \end{bmatrix} \right],
\]

(5-4)
\[X_\eta(\xi, \eta) = [\alpha(\xi, \eta) - 1 - \alpha(\xi, \eta)] \begin{bmatrix} P_0(\eta) \\ P_1(\eta) \end{bmatrix} + [\alpha_y(\xi, \eta)] \begin{bmatrix} P_0(\eta) \\ P_1(\eta) \end{bmatrix} + [Q_0(\xi) \ Q_1(\xi)] \begin{bmatrix} \beta_y(\xi, \eta) \\ -\beta_y(\xi, \eta) \end{bmatrix} - [\alpha_y(\xi, \eta) - \alpha_y(\xi, \eta)] \begin{bmatrix} Q_0(0) \\ Q_1(0) \end{bmatrix} + [Q_0(0) \ Q_1(0)] \begin{bmatrix} \beta_y(\xi, \eta) \\ -\beta_y(\xi, \eta) \end{bmatrix} \]

where

\[
\alpha_z(\xi, \eta) = \sum_{i=0}^{n} \sum_{j=0}^{n} a_{ij} B_{i,m}(\xi) B_{j,n}(\eta)
\]

\[
\alpha_y(\xi, \eta) = \sum_{i=0}^{m} \sum_{j=0}^{m} a_{ij} B_{i,m}(\xi) B_{j,n}(\eta)
\]

\[
\beta_z(\xi, \eta) = \sum_{i=0}^{m} \sum_{j=0}^{m} b_{ij} B_{i,m}(\xi) B_{j,n}(\eta)
\]

\[
\beta_y(\xi, \eta) = \sum_{i=0}^{m} \sum_{j=0}^{m} b_{ij} B_{i,m}(\xi) B_{j,n}(\eta)
\]

can be obtained from (5-2) and (5-3), and \(B_{j,n}'(t) = \frac{d}{dt} B_{j,n}(t) = n(B_{j-1,n}(t) - B_{j,n-1}(t))\). By the objective function, the gradient direction of the solution vector is determined by

\[
\frac{\partial \Delta}{\partial a_{i,j}} = \int_{\phi} [-(X_{\xi_n} X_{\eta_i} - X_{\eta_i} X_{\xi_n})] \frac{\partial X_{\eta_i}}{\partial a_{i,j}} X_{\xi_n} \frac{\partial X_{\xi_n}}{\partial a_{i,j}} X_{\eta_i} - \frac{\partial X_{\eta_i}}{\partial a_{i,j}} X_{\xi_n} \frac{\partial X_{\xi_n}}{\partial a_{i,j}} X_{\eta_i} \ d\xi d\eta.
\]

\[
\frac{\partial \Delta}{\partial b_{i,j}} = \int_{\phi} [-(X_{\xi_n} X_{\eta_i} - X_{\eta_i} X_{\xi_n})] \frac{\partial X_{\eta_i}}{\partial b_{i,j}} X_{\xi_n} \frac{\partial X_{\xi_n}}{\partial b_{i,j}} X_{\eta_i} - \frac{\partial X_{\eta_i}}{\partial b_{i,j}} X_{\xi_n} \frac{\partial X_{\xi_n}}{\partial b_{i,j}} X_{\eta_i} \ d\xi d\eta.
\]

Similar to the single parameter case, to compute the equations (5-7) and (5-8), we need to know \(\frac{\partial X_{\xi}}{\partial a_{i,j}}, \frac{\partial X_{\eta}}{\partial a_{i,j}}, \frac{\partial X_{\xi}}{\partial b_{i,j}}, \) and \(\frac{\partial X_{\eta}}{\partial b_{i,j}}\). They are derived from (5-4) and (5-5) as

\[
\frac{\partial X_{\xi}}{\partial a_{i,j}} = (P_0(\eta) - P_1(\eta)) \frac{\partial \alpha_z(\xi, \eta)}{\partial a_{i,j}}
\]

\[
- \{[Q_0(0) - Q_1(1) + (Q_0(0) + Q_1(1) - Q_0(1) - Q_0(1)) \beta_\eta(\xi, \eta)] \frac{\partial \alpha_y(\xi, \eta)}{\partial a_{i,j}} \}
\]

\[
\frac{\partial X_{\eta}}{\partial a_{i,j}} = (P_0(\eta) - P_1(\eta)) \frac{\partial \alpha_y(\xi, \eta)}{\partial a_{i,j}} + (P_0(\eta) - P_1(\eta)) \frac{\partial \alpha_y(\xi, \eta)}{\partial a_{i,j}}
\]

\[
- \{[Q_0(0) + Q_1(1) - Q_0(1) - Q_0(1)) \beta_\eta(\xi, \eta)] \frac{\partial \alpha_y(\xi, \eta)}{\partial a_{i,j}} \}
\]

(5-9)

(5-10)
\[
\frac{\partial X}{\partial b_{i,j}} = (Q_0(\xi) - Q_1(\xi)) \frac{\partial \beta(\xi, \eta)}{\partial b_{i,j}} + (Q_0(\xi) - Q_1(\xi)) \frac{\partial \beta(\xi, \eta)}{\partial b_{i,j}}
\]
\[
- (Q_0(0) + Q_1(0) - Q_0(1) - Q_1(0)) \frac{\partial \beta(\xi, \eta)}{\partial b_{i,j}}
\]
\[
- [(Q_0(1) - Q_1(1)) + (Q_0(0) + Q_1(1) - Q_0(0) - Q_1(0)) \alpha(\xi, \eta)] \frac{\partial \beta(\xi, \eta)}{\partial b_{i,j}}
\]

(5-11)

\[
\frac{\partial X}{\partial b_{i,j}} = (Q_0(\xi) - Q_1(\xi)) \frac{\partial \beta(\xi, \eta)}{\partial b_{i,j}}
\]
\[
- (Q_0(0) + Q_1(0) - Q_0(1) - Q_1(0)) \frac{\partial \beta(\xi, \eta)}{\partial b_{i,j}}
\]
\[
- [(Q_0(1) - Q_1(1)) + (Q_0(0) + Q_1(1) - Q_0(0) - Q_1(0)) \alpha(\xi, \eta)] \frac{\partial \beta(\xi, \eta)}{\partial b_{i,j}}
\]

(5-12)

where

\[
\frac{\partial \alpha(\xi, \eta)}{\partial a_{i,j}} = B_{i,m}(\xi)B_{j,n}(\eta), \quad \frac{\partial \beta(\xi, \eta)}{\partial b_{i,j}} = B_{i,m}(\xi)B_{j,n}(\eta).
\]

Fig. 5-1 depicts the grid generation result of Example III by optimizing the planar Coons patch of two-parameter blending functions (\(n = m = 3\)). We initially set

\[
(a_{i,j})_{4 \times 4} = \begin{bmatrix}
1 & 1 & 1 & 1 \\
2/3 & 2/3 & 2/3 & 2/3 \\
1/3 & 1/3 & 1/3 & 1/3 \\
0 & 0 & 0 & 0
\end{bmatrix}
\]

and

\[
(b_{i,j})_{4 \times 4} = \begin{bmatrix}
1 & 2/3 & 1/3 & 0 \\
1 & 2/3 & 1/3 & 0 \\
1 & 2/3 & 1/3 & 0 \\
1 & 2/3 & 1/3 & 0
\end{bmatrix}.
\]

Their related \(\alpha(\xi, \eta)\) and \(\beta(\xi, \eta)\) are displayed in Fig. 5-1b. When the functional optimization is completed, they become

\[
(a_{i,j})_{4 \times 4} = \begin{bmatrix}
1 & 1 & 1 & 1 \\
0.4149 & 0.1328 & 0.0963 & 0.3666 \\
0.0899 & -0.1294 & -0.5643 & -0.5712 \\
0 & 0 & 0 & 0
\end{bmatrix}
\]

and

\[
(b_{i,j})_{4 \times 4} = \begin{bmatrix}
1 & 0.6612 & 0.3255 & 0 \\
1 & 0.6146 & 0.2382 & 0 \\
1 & 0.4619 & -0.0418 & 0 \\
1 & 0.3446 & -0.1754 & 0
\end{bmatrix}.
\]

with which the final \(\alpha(\xi, \eta)\) and \(\beta(\xi, \eta)\) are shown in Fig. 5-1d.
Fig. 5-1  Example III – functional optimization using two-parameter blending functions
6. Progressive Optimization

Because our objective function in the functional optimization is concave (allowing many local minima — it is not the form of our objective function that leads these local minima; they are tightly related to the given boundary curves), the success of the numerical optimization algorithm depends critically on the initial position of the solution vector. We usually take the bilinear interpolation as an initial position of the solution vector; it however may be a very unsatisfying one to some strongly concaved boundaries (e.g., the one shown in Fig. 6-1a). “Guessing” a good initial vector is hard. The basic idea we take to overcome this difficulty is to progressively achieve the functional optimum by gradually deforming a rectangle boundary region into the region $\Omega$ bounded by the given curves, which we discuss in detail in this section.

The initial shape, a rectangle, does not generate overlapping with a bilinear Coons patch $X^0(\xi, \eta)$. When deforming the rectangle into the final shape $\Omega$ by a linear interpolation, we check if overlap occurs and, once it is detected, the numerical optimization method presented is applied to $X^0(\xi, \eta)$ to determine a new Coons patch mapping $X^1(\xi, \eta)$ without self-overlap; the deformation will then continue. The deformation and functional optimization are applied alternatively on $X^i(\xi, \eta)$ (where $i$ represents the Coons patch mapping determined after $i$ times of the numerical optimization) until the final non-self-overlapping planar Coons patch $X^f(\xi, \eta)$ of $\Omega$ is obtained. We use the box $\{R_{00}, R_{01}, R_{11}, R_{10}\}$ of $\Omega$ as the initial rectangle region, where $R_{00}$, $R_{01}$, $R_{11}$, $R_{10}$ are its four corner points in an anti-clockwise sense. Thus, its four boundary curves are

$$
Q_{R0}(\xi) = \xi R_{01} + (1 - \xi) R_{00} \\
Q_{R1}(\xi) = \xi R_{11} + (1 - \xi) R_{10} \\
P_{R0}(\eta) = \eta R_{10} + (1 - \eta) R_{00} \\
P_{R1}(\eta) = \eta R_{11} + (1 - \eta) R_{01}
$$

(6-1)

where $Q_{R0}(\xi) - Q_0(\xi)$, $Q_{R1}(\xi) - Q_1(\xi)$, $P_{R0}(\eta) - P_0(\eta)$, and $P_{R1}(\eta) - P_1(\eta)$ are related. Therefore, the four boundary curves of $X^i(\xi, \eta)$ are

$$
Q'_0(\xi) = \lambda_i Q_0(\xi) + (1 - \lambda_i)(\xi R_{01} + (1 - \xi) R_{00}) \\
Q'_1(\xi) = \lambda_i Q_1(\xi) + (1 - \lambda_i)(\xi R_{11} + (1 - \xi) R_{10}) \\
P'_0(\eta) = \lambda_i P_0(\eta) + (1 - \lambda_i)(\eta R_{10} + (1 - \eta) R_{00}) \\
P'_1(\eta) = \lambda_i P_1(\eta) + (1 - \lambda_i)(\eta R_{11} + (1 - \eta) R_{01})
$$

(6-2)

where $\lambda_i$ is the deformation factor, or the time, when the functional optimization is applied to $X^i(\xi, \eta)$ ($\lambda_i \in [0, 1]$). At the beginning of the deformation, $\lambda_i = 0$; after the deformation is completed, $\lambda_i = 1$. Also, we can get
\[
\frac{\partial}{\partial \xi} Q_0^i(\xi) = \lambda_i Q_0^i(\xi) + (1 - \lambda_i)(R_{01} - R_{00}) \\
\frac{\partial}{\partial \xi} Q_1^i(\xi) = \lambda_i Q_1^i(\xi) + (1 - \lambda_i)(R_{11} - R_{10}) \\
\frac{\partial}{\partial \eta} P_0^i(\eta) = \lambda_i P_0^i(\eta) + (1 - \lambda_i)(R_0 - R_{00}) \\
\frac{\partial}{\partial \eta} P_1^i(\eta) = \lambda_i P_1^i(\eta) + (1 - \lambda_i)(R_{11} - R_{10})
\]
\[(6-3)\]

Using \( Q_0^i(\xi) \), \( Q_1^i(\xi) \), \( P_0^i(\eta) \), \( P_1^i(\eta) \), \( \frac{\partial}{\partial \xi} Q_0^i(\xi) \), \( \frac{\partial}{\partial \xi} Q_1^i(\xi) \), \( \frac{\partial}{\partial \eta} P_0^i(\eta) \), and \( \frac{\partial}{\partial \eta} P_1^i(\eta) \) in (6-2) and (6-3) to take place of \( Q_0(\xi) \), \( Q_1(\xi) \), \( P_0(\eta) \), \( P_1(\eta) \), \( Q_0^i(\xi) \), \( Q_1^i(\xi) \), \( P_0^i(\eta) \), and \( P_1^i(\eta) \) in the equations of section 5, the functional optimum of \( X^i(\xi, \eta) \) can be determined by the same method.

During the deformation, the deformation factor increases from zero to one adaptively to the value increase of the objective function. The overall procedure of progressive optimization is given in pseudo-code in Algorithm ProgressiveOptimization() below. In Example IV (shown in Fig. 6-1), the non-self-overlapping planar Coons patch cannot be obtained by the pure numerical optimization even after iterating 10000 times; using Algorithm ProgressiveOptimization(), we obtain a final result without self-overlapping by only 30 applications of the numerical optimization routine – in each time, less than 10 iterations are needed. The progressive results are shown in Fig. 6-2.

**Algorithm** ProgressiveOptimization ( \( \Omega \) )

**Input:** A region \( \Omega \) in the \( u-v \) parametric space.

**Output:** The non-self-overlap planar Coons patch \( X^i(\xi, \eta) \) on \( \Omega \).

1. Compute the bounding box of \( \Omega \), and use it to generate \( Q_{00}(\xi) \), \( Q_{01}(\xi) \), \( P_{00}(\eta) \), and \( P_{01}(\eta) \);
2. Build \( X^0(\xi, \eta) \) on \( Q_{00}(\xi) \), \( Q_{01}(\xi) \), \( P_{00}(\eta) \), and \( P_{01}(\eta) \) as a bilinear planar Coons patch;
3. \( i \leftarrow 1 \) and \( \lambda_0 \leftarrow 0 \);
4. do{
5. \( \Delta \lambda \leftarrow 2(1 - \lambda_{i-1}) \);  
6. do{
7. \( \Delta \lambda \leftarrow \Delta \lambda / 2 \), and \( \lambda_i \leftarrow \lambda_{i-1} + \Delta \lambda \);
8. Change the shape of \( X^i(\xi, \eta) \) by \( \lambda_i \), and compute the objective function \( A \) of \( X^i(\xi, \eta) \);
9. Compute the area \( \widetilde{A} \) of \( X^i(\xi, \eta) \);
10. }while( (\( A / \widetilde{A} > \tau \)));
11. Compute the numerical optimum of blending functions in \( X^i(\xi, \eta) \);
12. \( i \leftarrow i + 1 \);
13. }while( \( \lambda_{i-1} < 1 \));
14. \( X^f(\xi, \eta) \leftarrow X^{i-1}(\xi, \eta) \);
15. return \( X^f(\xi, \eta) \);

(* in our testing, we choose \( \tau = 0.5\% \) )
Fig. 6-1  Example IV – result of progressive optimization \( (n = m = 3) \)
7. Extension of Shape Control

In the previous parts of this paper, the objective function of optimization (4-3) does not consider the shape control of each element. Actually, it is possible to add a shape control term in the objective function. The basic idea that if \( X_\xi \cdot X_\eta \to 0 \) was maintained all over the patch, the shape of every element in the grid could be guaranteed in the \( \xi - \eta \) plane. Thus, we add a new term

\[
B = \iint_{\eta} (X_\xi X_\eta + X_\eta X_\xi)^2 \, d\xi d\eta, \quad (7-1)
\]

to the objective function. The modified objective function is

\[
J = w_A A + w_B B \quad (7-2)
\]

where \( A \) is as given in (4-3), and \( w_A, w_B \) are the factors to balance the weight between the term \( A \) and the term \( B \). When the term \( B \) is minimized to zero, the \( X_\xi \cdot X_\eta \to 0 \) is guaranteed all over the patch.
In order to minimize the objective function, we need to have its gradients with respect to the solution vector. By equation (7-1), we have

\[
\frac{\partial B}{\partial a_{i,j}} = \int_{\psi} \left( 2(X_{\xi}, X_{\eta} + X_{\xi} X_{\eta}) \frac{\partial X_{\xi}}{\partial a_{i,j}} + X_{\eta} X_{\xi} \right) d\xi d\eta.
\] (7-3)

\[
\frac{\partial B}{\partial b_{i,j}} = \int_{\psi} \left( 2(X_{\xi}, X_{\eta} + X_{\xi} X_{\eta}) \frac{\partial X_{\xi}}{\partial b_{i,j}} + X_{\eta} X_{\xi} \right) d\xi d\eta.
\] (7-4)

Thus, together with equations (5-7) and (5-8), the gradients of \( J \) with respect to \( a_{i,j} \) and \( b_{i,j} \) are computed by

\[
\frac{\partial J}{\partial a_{i,j}} = w_A \frac{\partial A}{\partial a_{i,j}} + w_B \frac{\partial B}{\partial a_{i,j}} \quad \text{and} \quad \frac{\partial J}{\partial b_{i,j}} = w_A \frac{\partial A}{\partial b_{i,j}} + w_B \frac{\partial B}{\partial b_{i,j}}.
\] (7-5)

The comparison of the non-self-overlapping Coons patch generation with and without shape control is given in the following figures. Fig. 7-1 shows the bilinear Coons patch before optimization. Obviously, the patch is self-overlapped. Fig. 7-2a gives the optimized patch with weights \( w_A = 1.0 \) and \( w_B = 0 \) – the shape control is not cared (the result blending functions without shape control are shown in Fig. 7-2b). The mesh is stretched in the middle. Fig. 7-2c and 7-2d illustrate the result with shape control by changing \( w_B \) from 0 to \( 10^{-13} \), which leads to less stretch inside the Coons patch.
(c) after optimization without shape control
\( w_A = 1.0 \text{ and } w_B = 0 \)

(d) \( \alpha(\xi,\eta) \) and \( \beta(\xi,\eta) \) in (c)

(e) after optimization with shape control
\( w_A = 1.0 \text{ and } w_B = 10^{-13} \)

(f) \( \alpha(\xi,\eta) \) and \( \beta(\xi,\eta) \) in (e)

Fig. 7-2 Example V – optimization with vs. without shape control
This shape control idea can be further extended to control the shape of elements on the given parametric surface. If $S_{\xi} \cdot S_{\eta} \rightarrow 0$ was maintained all over the patch, the shape of every element in the grid could be guaranteed on the parametric surface $S$. The term $B$ of the objective function could be modified to

$$B^* = \int \int_{Q} \left( S_{\xi} S_{\eta_x} + S_{\eta} S_{\eta_\xi} + S_{\xi} S_{\eta_\eta} \right)^2 d\xi d\eta$$

to achieve this condition. Therefore, the new objective function might be $J^* = w_A A + w_S S$.

8. Experimental Results and Discussion

Fig. 8-1 gives the algebraic grid generation results of trimmed surfaces in Example I and II (initially given in Fig. 1-2), and their final blending functions ($n = m = 3$) of the non-self-overlapping planar Coons patch are also shown. When the shape of the trimmed surface in the parametric space is very convoluted (e.g., an $n$-sided or with a hole – such as Example V shown in Fig. 8-2a), the given region is subdivided into several 4-sided sub-patches (Fig. 8-2b), where all patches satisfy Assumption 3.1; then the approach presented in this paper can be applied to generate the final algebraic grids (Fig. 8-2c and 8-2d show the result of example V).

When applying the functional optimization to obtain the algebraic equation of the Coons patch, we should choose the order of blending functions carefully. If the order of blending functions is lower than the order of the given four boundary curves, the functional optimization may not be convergent; however, higher order polynomials tend to make the final shape of the blending functions vibrate violently. Thus, we usually let the order of blending functions to be the same as that of the boundary curves or just one order higher.
Fig. 8-1 Algebraic grid generation results of Example I and II
9. Conclusion

The ability to generate a grid system in a 4-sided region bounded by parametric boundary curves of any form with only $C^1$ continuity is a significant advantage of the Coons patch method over other algebraic methods for building a structured grid. This not only averts the singularity of elliptic PDE methods when only $C^1$ continuous boundary available, but also avoids the error generated when converting generic parametric $C^1$ boundary curves into curves with a specified representation form. However, the self-overlapping phenomenon frequently encountered in Coons patch mapping has been perplexing both theoreticians and practitioners for a long time and limiting its usage in many scientific and engineering practices. In this paper, we present an algorithm that uses the functional optimization method to determine the blending functions in a Coons patch so that the self-overlap can be prevented. Our initial test results are encouraging: in a variety of cases where self-
overlapping occurs if linear or naïve blending functions were used, the found blending functions after the functional optimization successfully avert the self-overlapping. A possible extension is also given to demonstrate how to control the shape of elements by adding a new term on the objective function. Coupled with any mesh smoothing methods [2], our algorithm provides a promising meshing tool in engineering.

The main disadvantage of our Coons patch method is the computing time. The time cost of examples in this paper is shown in Table 9-1. Usually, several minutes are needed. All tests are performed on a PIII 500 PC with a program written in Java. In the current implementation, we use a very primitive numerical method to compute the functional optimization. It is believed that with more efficient optimization algorithms and with the increasing processing power available on every desktop, the running time can be shortened significantly. Moreover, the following topics or improvements are worth future research:

- In our extension of element shape control, the shapes of elements are controlled in the $\xi-\eta$ plane; however, as described at the end of section 7, our experiment has already shown the possibility of controlling the shape of elements on the given trimmed parametric surface.
- Also, it will be interesting to see if the ideas of this paper can be extended into three-dimensional space to solve the algebraic grid generation problem in a given closed space using a Coons solid. Then, the governing equation may come from the same idea as Equation (3-1) by detecting some properties of the Coons solid in a virtual newly added axis direction.

### 10. Reference

Appendix A

Lemma

The Coons patch \( X(\xi, \eta) \) is a graph-mapping if and only if there is no any singular point in the square \([0, 1] \times [0, 1]\).

Proof. Let us argue the \( X(\xi, \eta) \) by \( X^*(\xi, \eta) = \begin{bmatrix} U^*(\xi, \eta) = U(\xi, \eta) \\ V^*(\xi, \eta) = V(\xi, \eta) \\ W^*(\xi, \eta) \end{bmatrix} \) with \( W^*(\xi, \eta) = a\xi + b\eta \) for some real number \( a \) and \( b \). By properly choosing \( a \) and \( b \), one can enforce \( X^*(\xi, \eta) \) to have normal vector everywhere, thus it is a smooth regular surface in the \( u \times v \times w \) space. Suppose first that \( X(\xi, \eta) \) is not a graph-mapping. This means that there exist two distinct pairs \( (\xi_0, \eta_0) \in [0,1] \times [0,1] \) and \( (\xi_1, \eta_1) \in [0,1] \times [0,1] \) such that \( (X^*(\xi_0, \eta_0), V^*(\xi_0, \eta_0)) = (X^*(\xi_1, \eta_1), V^*(\xi_1, \eta_1)) \). By properly selecting \( a \) and \( b \), one can also ensure that \( W^*(\xi_0, \eta_0) \neq W^*(\xi_1, \eta_1) \). Let us intersect \( X^*(\xi, \eta) \) with a plane \( \Pi \) that is parallel to the \( u-w \) plane and contains the two points

\[
p_0 = (U^*(\xi_0, \eta_0), V^*(\xi_0, \eta_0), W^*(\xi_0, \eta_0)) \quad \text{and} \quad p_1 = (U^*(\xi_1, \eta_1), V^*(\xi_1, \eta_1), W^*(\xi_1, \eta_1)),
\]

resulting in a regular curve \( \sigma \). Consider the portion \( \sigma^* \) of \( \sigma \) between the two points. Since \( \sigma^* \) is regular and bounded, it must have a \( u \)-extreme point \( p = (U^*(\xi^*, \eta^*), V^*(\xi^*, \eta^*), W^*(\xi^*, \eta^*)) \) where the normal vector \( n \) to the curve is parallel to the \( u \)-axis, as shown in Fig. A-1a. Since the projection of the normal \( N \) to the surface \( X^*(\xi, \eta) \) at point \( p \) in plane \( \Pi \) can be easily seen to identify with \( n \), we have \( N \cdot w = 0 \). This translates to

\[
U^*_{\xi}(\xi^*, \eta^*)V^*_{\eta}(\xi^*, \eta^*) = U^*_{\eta}(\xi^*, \eta^*)W^*_{\xi}(\xi^*, \eta^*),
\]

i.e., \( U^*_{\xi}(\xi^*, \eta^*)V^*_{\eta}(\xi^*, \eta^*) = U^*_{\eta}(\xi^*, \eta^*)W^*_{\xi}(\xi^*, \eta^*) \). This means \( (\xi^*, \eta^*) \) is a singular point of \( X(\xi, \eta) \).

Conversely, let \( (\xi^*, \eta^*) \) be a singular point of \( X(\xi, \eta) \); hence, \( U^*_{\xi}(\xi^*, \eta^*)V^*_{\eta}(\xi^*, \eta^*) = U^*_{\eta}(\xi^*, \eta^*)W^*_{\xi}(\xi^*, \eta^*) \).

Consequently, the normal \( N \) to the surface \( X^*(\xi, \eta) \) at \( (\xi^*, \eta^*) \) is perpendicular to the \( w \)-axis. Without loss of generality, we can assume \( N \) is parallel to the \( u \)-axis. Intersecting \( X^*(\xi, \eta) \) with the plane \( w = V^*(\xi^*, \eta^*) \), we obtain a regular curve \( \sigma \). As \( p^* = (U^*(\xi^*, \eta^*), V^*(\xi^*, \eta^*), W^*(\xi^*, \eta^*)) \) is a local \( u \)-extreme point on this curve,
one can find a real number $\delta > 0$ such that the vertical line $u = U^\star(\xi^\star, \eta^\star) - \delta$ intersects $\sigma$ at least twice (assuming $p^\star$ is a $u$-maximum point). Let

$$p_0 = (U^\star(\xi_0, \eta_0), V^\star(\xi_0, \eta_0), W^\star(\xi_0, \eta_0))$$

and

$$p_1 = (U^\star(\xi_1, \eta_1), V^\star(\xi_1, \eta_1), W^\star(\xi_1, \eta_1))$$

be two such intersection points for some $(\xi_0, \eta_0) \neq (\xi_1, \eta_1)$, as shown in Fig. A-1b. Obviously, we have

$$(U^\star(\xi_0, \eta_0), V^\star(\xi_0, \eta_0)) = (U^\star(\xi_1, \eta_1), V^\star(\xi_1, \eta_1)).$$

Since $(U(\xi, \eta), V(\xi, \eta)) = U^\star(\xi, \eta), V^\star(\xi, \eta)$, we conclude that $X(\xi, \eta)$ maps two distinct points in the $\xi-\eta$ domain to a same point in the region $\Omega_X$. This completes the proof.
